Heart Rate

Normal Heart Rate by Age (beats/minute)
Reference: PALS Guidelines, 2015

Age	Awake Rate	Sleeping Rate
Neonate (<28 d)	100-205	90-160
Infant (1 mo–1 y)	100-190	90-160
Toddler (1-2 y)	98-140	80-120
Preschool (3-5 y)	80-120	65-100
School-age (6-11 y)	75-118	58-90
Adolescent (12-15 y)	60-100	50-90

Respiratory Rate

Normal Respiratory Rate by Age (breaths/minute)
Reference: PALS Guidelines, 2015

Age	Normal Respiratory Rate
Infants (<1 y)	30-53
Toddler (1-2 y)	22-37
Preschool (3-5 y)	20-28
School-age (6-11 y)	18-25
Adolescent (12-15 y)	12-20

Blood Pressure

Normal Blood Pressure by Age (mm Hg)
Reference: PALS Guidelines, 2015

Age	Systolic Pressure	Diastolic Pressure	Systolic Hypotension
Birth (12 h, <1000 g)	39-59	16-36	<40-50
Birth (12 h, 3 kg)	60-76	31-45	<50
Neonate (96 h)	67-84	35-55	<60
Infant (1-12 mo)	70-104	37-56	<70
Toddler (1-2 y)	86-106	42-65	<70 + (age in years x 2)
Preschooler (3-5 y)	89-112	46-72	<70 + (age in years x 2)
School-age (6-9 y)	97-115	51-76	<70 + (age in years x 2)
Preadolescent (10-11 y)	102-120	61-80	<90
Adolescent (13-15 y)	110-131	64-85	<90

For diagnosis of hypertension refer to the NHBPEP Reference tables: http://www.nhlbi.nih.gov/health-pro/guidelines/current/hypertension-pediatric-jnc-4/blood-pressure-tables.

Table 3. Normal Vital Signs For Age Of Pediatric Patients.

Age	Heart Rate (bpm)	Respiratory Rate (bpm)	Systolic Blood Pressure (mm Hg)	Diastolic Blood Pressure (mm Hg)
Newborn	90-180	30-50	60 ± 10	37 ± 10
1-5 months	100-180	30-40	80 ± 10	45 ± 15
6-11 months	100-150	25-35	90 ± 30	60 ± 10
1 year	100-150	20-30	95 ± 30	65 ± 25
2-3 years	65-150	15-25	100 ± 25	65 ± 25
4-5 years	65-140	15-25	100 ± 20	65 ± 15
6-9 years	65-120	12-20	100 ± 20	65 ± 15
10-12 years	65-120	12-20	110 ± 20	70 ± 15
13+ years	55-110	12-18	120 ± 20	75 ± 15

PEARS®

Vital Signs in Children

Normal Heart Rates (per Minute) by Age*

Age	Awake Rate	Mean	Sleeping Rate
Newborn to 3 months	85 to 205	140	80 to 160
3 months to 2 years	100 to 190	130	75 to 160
2 years to 10 years	60 to 140	80	60 to 90
>10 years	60 to 100	75	50 to 90

Normal Respiratory Rates by Age†

Age	Breaths per Minute
Infant (<1 year)	30 to 60
Toddler (1 to 3 years)	24 to 40
Preschooler (4 to 5 years)	22 to 34
School-age child (6 to 12 years)	18 to 30
Adolescent (13 to 18 years)	12 to 16

Normal Blood Pressures by Age‡

Age	Systolic Blood Pressure (mm Hg)		Diastolic Blood Pressure (mm Hg)	
	Female	Male	Female	Male
Neonate (1 day)	60 to 76	60 to 74	31 to 45	30 to 44
Neonate (4 days)	67 to 83	68 to 84	37 to 53	35 to 53
Infant (1 month)	73 to 91	74 to 94	36 to 56	37 to 55
Infant (3 months)	78 to 100	81 to 103	44 to 64	45 to 65
Infant (6 months)	82 to 102	87 to 105	46 to 66	48 to 68
Infant (1 year)	86 to 104	85 to 103	40 to 58	37 to 56
Child (2 years)	88 to 105	88 to 106	45 to 63	42 to 61
Child (7 years)	96 to 113	97 to 115	57 to 75	57 to 76
Adolescent (15 years)	110 to 127	113 to 131	65 to 83	64 to 83

Threshold by Age of Systolic Blood Pressure Indicating Hypotension

Age	Systolic Blood Pressure
Term neonates (0 to 28 days)	Less than 60 mm Hg
Infants (1 to 12 months)	Less than 70 mm Hg
Children 1 to 10 years (5th blood pressure percentile)	Less than 70 + (age in years × 2) mm Hg
Children >10 years	Less than 90 mm Hg

Age Group	Heart Rate	Respirations	Systolic BP
Preterm	120 – 180	50 – 70	40 – 60
Newborn (0 to 1 Month)	100 – 160	35 – 55	50 – 70
Infant (1 to 12 Months)	80 – 140	30 – 40	70 – 100
Toddler (1 to 3 Years)	80 – 130	20 – 30	70 – 110
Preschool (3 to 6 Years)	80 – 110	20 – 30	80 – 110
School Age (6 to 12 Years)	70 – 100	18 – 24	80 – 120
Adolescents (12+ Years)	60 – 90	14 - 22	100 – 120

Vital sign thresholds are incorporated into various screening tools to help identify those children at higher risk of serious medical or surgical illness (1¢ÃÂÂ4). To effectively utilize vital sign data in children, however, it may be more useful to identify the magnitude of deviation from the expected vital sign distribution, considering the child¢ÃÂÂs age and location of care [e.g., emergency department (ED) versus intensive care unit (ICU)], rather than determining if the vital sign value is abnormal. Since most current scoring tools consider vital signs as dichotomous variables (i.e., ¢ÃÂÂnormal¢ÃÂÂ or ¢ÃÂÂabnormal¢ÃÂÂ) within relatively wide age ranges, it is not surprising that most triage and scoring tools have performed poorly even though they are significantly associated with the outcome of interest (4¢ÃÂÂ7). Most screening tools use vital sign thresholds that fail to consider the physiologic stress response of a child seen in the ED. Thus, the upper ¢ÃÂÂnormal¢ÃÂÂ vital sign thresholds observed in ED patients were higher than observed in children who were hospitalized on the ward or who were ambulatory (8¢ÃÂÂ10). The value of using empirically derived ED vital sign thresholds was demonstrated in a study of a pediatric ED sepsis screening tool that incorporated temperature (TMP) adjustment for heart rate (HR) and respiratory rate (RR) (11). The tool¢ÃÂÂs positive predictive value was 48.7%, almost threefold better than using the consensus systemic inflammatory response syndrome (SIRS) criteria (12), with no loss of sensitivity (11). In sepsis, early identification of children at risk is a key recommendation for optimal management (13) since early implementation of protocol-guided sepsis care decreased sepsis-related organ dysfunction, hospital and ICU length of stay, and mortality (14¢ÃÂÂ16). Clinical judgment alone misses approximately 27% of septic children seen in the ED (17). Using vital sign data with current parameters is limited by the high rate of tool activation; almost 17% of febrile or hypothermic children in the ED met alert criteria, but only 2.5% of these children had severe sepsis or septic shock (17). Similarly, more than 90% of febrile children in the ED meet vital sign criteria for SIRS (5), and ~12% of all ED children triggered an alert based on tachycardia alone (4). These data suggest that current sepsis screening tools identify too many at-risk children, leading to alert fatigue (18) and reluctance to use the tool. Recent studies empirically derived centile ranks and, in some cases, z-scores for vital sign parameters by age (9, 11). The rationale for considering the vital sign parameter¢ÃÂÂs z-score or centile rank rather than ¢ÃÂÂnormal¢ÃÂÂ versus ¢ÃÂÂabnormal¢ÃÂÂ is based on the enhanced statistical power of the former over the latter (19, 20). We hypothesized that current pediatric HR and RR vital sign thresholds used in Pediatric Advanced Life Support (PALS) or derived from low-acuity ED patients do not accurately reflect empirically derived HR and RR centiles. To develop empirically derived thresholds that could be incorporated into ED screening tools and may inform monitor alarm limits, we analyzed a very large multi-institutional database to derive HR and RR centile ranks and z-scores stratified by age in children presenting to the ED. Ultimately, our goal is to derive HR and RR data that can be applied as continuous variables in electronic health record (EHR)-based tools to stratify children into risk groups or used as threshold limits in paper-based triage tools. Empirically derived vital sign distributions also may better determine alarm limits in different aged children to reduce alarm fatigue and may be useful to stratify children into risk groups for clinical trials. The latter two exclusion types (collectively ~0.4% of cases) were excluded since we did not want to include children who were more likely to have very abnormal vital signs. A summary of the selection and exclusion criteria used to determine the final data set for our study is given in Data Sheet S2 in Supplementary Material with details on specific diagnostic exclusions in Data Sheet S3 in Supplementary Material. A sensitivity analysis of the effects of these exclusions on the final modeled centile results was conducted, as described below. Model Validation To test model reproducibility, we performed a stratified split-sample validation whereby the full data set used for each vital sign was divided into a ¢ÃÂÂtraining¢ÃÂÂsubset consisting of two-thirds of randomly selected records from each age group, and a ¢ÃÂÂtest¢ÃÂÂ data subset consisting of the remaining one-third of records. The training subset was modeled by GAMLSS to generate centile cutoffs, and the percentage of records with vital sign values above and below these modeled cutoffs for the 95th, 99th, 5th, and 1st centiles, respectively, were compared between the training and test data subsets using exact chi-square tests. Holm (step-down Bonferroni) (28) corrections, performed separately for HR and RR, were used to adjust for the multiple testing of each metric. Sensitivity Analysis To determine the effect of excluding encounters classified as ¢ÃÂÂTrauma Center,¢ÃÂÂ or those where the patient had a diagnosis of a chronic heart or respiratory condition, the modeling of HR and RR distributions was repeated including these encounters. The resultant modeled centile values, rounded to the nearest whole number for HR and RR, were then compared between datasets of children with and without exclusions. Table 3. Validation of the vital results of the signs centilhetical modeling. Table 3 also shows the high general agreement between the modeled centiles and the empirical data. Ideally, the groups of centiles modeled â € œcon99â € and â € œTRADUCE1â € should identify each of the empirical data, while the groups â € œConcentration 95â € and â € They should identify each around 5%. The deviations between the modeled and empirical percentages are evident only in the RR â € œplicate5â € and â € œatraãda1â € (which identify around 3.9 and 0.7% of the corresponding empirical data for these groups). Centile Tables and Z-SCOR By age group for HR and RR as centiles stand standardized (z-scores) ranging from â^’3.0 to +3.0 sds for RR and RR. Table 4. Cardãaca Rate (HR, BPM) Centiles by age. Sensitivity analysis Each sensitivity analysis shared centiles modeled between data sets with and without predefined exclusions for 11 levels and 40 categories of age (as presented in pictures 4 and 5). Our finding of a single discrepancy of 440 combinations of centiles and age for RR and four for RR, with differences of only 1 bpm for HR and 1 breathing/min for each RR, demonstrates that our choice to exclude these encounters resulted in an insignificant effect in the values of centiles modeled compared to those obtained without exclusions. Table 5. Respiratory rate (RR, breathing/minute) Centiles by age. Comparison with the current and guide vital sign lower than the values determined by Oâ € ™ Leary et al. (10), and the 95 cã © ntimos for HR were 13 to 24 bpm higher than the Oâ € ™ Leary values, while the child age pals recommended upper and lower lower RR (29) were above and below the 95th and 5th centiles, respectively. The empirically derived 95th centile RR in infants (Figure 3B) was also higher by 7¢ÂÂÂ11 breaths/min than O¢ÂÂÂLeary¢ÂÂÂs data, whereas the 50th and 5th centile were similar. The PALS recommended upper RR in infants was similar to the empirically derived 95th centile range, although by 10 months of age, it steadily exceeded the empirically derived 95th centile. The lower PALS RR limit was 6¢ÂÂÂ10 breaths/min above the empirically derived 5th centile and was similar to the 50th centile by 7 months of age. Figure 3. (A) The derived 5th, 50th, and 95th HR centiles by age compared with similar centiles derived by O¢ÂÂÂLeary et al. (10) The Pediatric Advanced Life Support (PALS) (29) upper and lower HR limits are also shown (dashed lines). The smaller panel shows the centiles from 0 to 12 months of age. (B) The derived 5th, 50th, and 95th RR centiles by age compared with similar centiles derived by O¢ÂÂÂLeary et al. (10). The PALS (29) upper and lower RR limits are also shown (dashed lines). The smaller panel shows the centiles from 0 to 12 months of age. In children (¢ÂÂ¥Â1 year), Figure 3A shows substantial discrepancy between the empirically derived 95th centile HR and O¢ÂÂÂLeary¢ÂÂÂs (10) centile HR values up to around 10 years of age. The fifth centile for all three sets of data are similar, but the PALS upper HR limits are below the empirically derived 95th centile and are between the 50th and 75th centile for age up to ~6 years old (23¢ÂÂÂ44 bpm lower from 1 through 6 years of age). Similarly, the empirically derived 95th centile RR (Figure 3B) is 3¢ÂÂÂ6 breaths/min higher than the PALS and O¢ÂÂÂLeary values up to 4¢ÂÂÂ5 years of age. Discussion We hypothesized that empirically derived HR and RR distributions would deviate from PALS recommended distributions, and values derived from a low-acuity population of children seen in the ED. Ideally, an effective le ,senoicavresbo 000,611 ed s¡Âm ed n³Ãicazilatipsoh ed artseum anu ne euq etnednerpros se on ,otnat ol roP .)B3 arugiF(ojab etnemlamrona RR nu nagnet seroyam s©Ãbeb sol ed %05 le atsah euq atsah ¡Ãralaverbos es n©Ãibmat SLAP soiretirc ed osu lE .dade ed so±Ãa 21 atsah ed etnemacirÂpme odavired rolav le nedecxe etnemlareneg seroirefni RR SLAP ed serolav sol euq sartneim ,setnecseloda sohcum a aÃracifidierbos avisecxe roirepus RR SLAP ed etimÃl lE .dade ed so±Ãa 4 atsah ed ejazidnerpa ed serolav sol y slaP sol euq otla s¡Âm se etnemacirÂpme odavired)B3 arugiF(RR elitneC °Â 59 le ,odom omsim leD .ogseir ne so±Ãin sol ed laicnatsus n³Ãicafitnedierbos anu a avell euq ol ,so±Ãa 6 ~ atsah ed dade al etnarud 57 y 05 ocirtn©Ãc le ertne nartneucne es y etnemacirÂpme sodavired 59 sortnec sol ed ojabed rop yum n¡Âtse seroirepus slaP CF al ed selarbmu soL .etnemacirÂpme navired es on y ,selativ songis ed adarepse n³Ãicubirtsid ailpma anu ,otnat ol rop ,y socig³Ãloisif sognar sednarg racraba euq ,soilpma etnemavitaler dade ed sognar ne selamron serolav napurga euq ay ,odatimil se aicnerefer ed sotxet sorto y)23(SLPA ,)92(SLAP rop sodadnemocer "selamron" selativ ongis ed selarbmu sol ed dadilitu al ,b ,a3 sarugiF sal ne ev es omoC .)13(ocitp©Ãs kcohs/areves sispes ed n³Ãicafitnedi al arap dadicificepse y dadilibisnes atla anu odatluser omoc nad n³Ãicneta ed sosecorp sol ed adalacse al ed arojem al y sadugaitnup s¡Âm ralucitra opiuqe ed senoicaulave sal ,ocinÃlc led n³Ãicafitnedi al noc RHE ne adasab n³Ãicceted ed atneimarreh anu ed n³Ãicanibmoc al euq nartseum setneicer sotad sol ,oibmac nE .ogseir ne so±Ãin sol sodot a euqifitnedi songis ne adasab lativ n³Ãicceted ed atneimarreh anu euq elbaborp ocop se euq reconocer etnatropmi se ,ograbme niS .)5(agitaf al ratrela a necudnoc euq sovitisop soslaf setneicap sodaisamed atimil euq opmeit la orooireted ed ogseir ne so±Ãin sol a ratceted arap dadilibisnes atla al rarbiliuqe ebed atneimarreh aL of human resources and 40% of the vital signs of RR observed in hospitalized children were outside the textbooks "Normales" distributions of vital signs and 38% of La FC and 30% of RR observations would have resulted in an increase in early warning scores (9). In the same way, in a of 40,356 ED visits at Colorado Children¢ÂÂÂs Hospital (5), 16.3% of the children had a fever (>38.5Â°ÂC) and 92.8% of these febrile children met SIRS vital sign criteria, as defined by the International Pediatric Sepsis Conference (12). Most of these children were discharged without any intervention. Several groups have used data from EHR¢ÂÂÂs to redefine the distribution of vital signs observed in children in the ED (8, 10) or hospital wards (9, 33). These analyses clearly show that the standard textbook and guideline distributions and thresholds for ¢ÂÂÂabnormal¢ÂÂÂ for vital signs do not reflect empirically observed distributions (9). However, our empirically derived centiles differ from centiles derived from a large (111,696) data set of children presenting to a single ED (10). Of note, this study (10) restricted its analysis to the lowest acuity children, whereas our analysis included all acuities, but excluded children seen in the ED who were subsequently admitted. This may better represent the distributions of vital signs seen in children brought to the ED, who are likely stressed by the ED environment, but who presumably are not critically or seriously ill and, thus, do not require hospitalization. We believe our empirically derived centiles based on a very large, multi-centered database of ED visits by children provide evidence-based vital sign parameters to use in either EHR or paper-based early warning scores, to set monitor alarm limits and to risk-stratify children for clinical trials or epidemiologic studies. Rather than using dichotomous threshold values, which are often set by consensus, to define ¢ÂÂÂnormal¢ÂÂÂ from ¢ÂÂÂabnormal,¢ÂÂÂ we believe that these data can lead to the development of more useful objective risk stratification tools. Although using vital sign parameter z-scores or centile ranks rather than ¢ÂÂÂnormal¢ÂÂÂ versus ¢ÂÂÂabnormal¢ÂÂÂ is complex, EHR systems can be programmed to analyze these to risk-stratify children, which enhances the statistical power of analyzing continuous data rather than using a dichotomous threshold (19, 20). By necessity, dichotomizing a continuous physiologic variable into two categories anticipates an unrealistic step function for risk at the threshold level. For example, if the upper limit of normal HR is set at 180 bpm, then an infant with a HR of 179 bpm is considered ¢ÂÂÂnormal,¢ÂÂÂ even though this infant is not demonstrating the same physiologic response as the same aged infant with a HR of 120 bpm. The potential value of using risk-stratified assessment of vital signs was seen in an ED-based study of 1,750 febrile children evaluated using seven different vital sign modeling strategies to identify children with serious bacterial infections (34). The model that worked best utilized the degree of deviation of age-adjusted HR and RR from median values, with or without TMP correction. Centile and z-Scores Although we generated smooth curves for the individual vital signs, the raw vital sign distributions for RR shown in Figure 1 are not Gaussian but rather show a strong kurtosis and right-tailed skew. The skewed RR may represent an increased prevalence of disease processes (i.e., respiratory conditions), which lead to more frequent elevated RR values in children presenting to the ED compared with a population of healthy, normal children. We performed a stratified split-sample validation that showed (Table 3) for each vital sign metric there was no significant difference in the proportion of cases in the training versus the test subjects. TMP-Adjusted Vital Signs Most screening tools do not TMP adjust the HR or RR. It is well known that increased TMP increases metabolic demand, thus increasing HR and RR (33, 35, 36). Analysis of vital sign data in hospitalized children (not ICU) found a near linear increase in HR with increasing TMP of approximately 10 beats/min for each s¡Âm natisecen eS .socipÃta sotse ed otcapmi le etnemelbaborp natimil necelbatse es euq sednarg yum sotad sol oveun ed orep ,selamrona yum o soen³Ãrre selativ songis ed serolav noc so±Ãin ed sotad ed n³Ãisulcni al a ragul odad rebah edeup otsE .RR y HHRR arap amertxe n³Ãisulcxe ed soiretirc razilitu somigelE .)83(lairetra n³Ãiserp al noc ev es omoc o±Ãin led arutla al y o±Ãamat le ne adasab elbazis lamron n³Ãicairav anu yah o±Ãa ed ognar reiuqlauc ed ortned euqrop etnemlaicepse ,oretne o±Ãa nu ed ortned so±Ãin riulcni ed otcapmi le netimil sotad sol ed odazivaus le y ednarg artseum al ed o±Ãamat le euq elbaborp eceraP .seroyam so±Ãin arap o±Ãa 1 ed sognar o)so±Ãa 2 norazilaer es is(sem 1 ed sognar somazilitu ,sasicerp sedade somaÃnet on euq otseuP senoicatimiL .)33(odidem PMT le ne selanoicida senoicairav ricudortni nedeup sortem³Ãmret setnerefid euq odnartsom ,latipsoh orto le ne odazilitu ortem³Ãmret omsim la ³Ãirifsnart senoicutitsni sal ed anu odnauc ³Ãicerapased euq ,senoicutitsni sal ertne PMT ed samargotsih setnerefid etnemavitacifingis ³Ãvresbo aifledaliF ed litnafnI latipsoH le y itannicniC ed litnafnI latipsoH le ne odazilaer oirotalubma oidutse nu ,etrap arto roP .n³Ãisufrep alam neneit euq setneicap ne etnemlaicepse ,lartnec PMT al ed etnemailpma rairav nedeup sojorrarfni e socin¡Ãpmit sPMT soL .so±Ãin sol ed esab al a laro PMT al nararapmoc euq soidutse socop norartnocne es)73(so±Ãin sol y sotluda sol ed socis¡Ãb setnenopmoc sol artnoc larefirep n³Ãicneta ed samargorp sol ed dutitcax al ed ocit¡Ãmetsis nemaxe etneicer nu nE .laropmet o ralixa airetra ed PMT sal arap rigerroc om³Ãc somaÃbas on y lartnec PMT al a laro PMT al ratsuja ed soruges somab¡Ãtse on orep ,RR y RH ne PMT ed otcefe le razilana somaenalP .)33(so±Ãa 81 a 41 ed 8 sal a etnerf odargitneC odarg rop setnatcal ne so±Ãa 71 a 51 ed sonamuh sosrucer sol ed otnemua nu noc ,dade al n°Ãges rairav ecerap otnemua le euqnua ,PMT al ne n³Ãicartnecnoc al ed otnemua lE to determine whether the use of thresholds of vital signs empirically gave rise to a lower sensitivity to identify high -risk children. Our previous analysis using highly derived vital signs thresholds based on data based on data A Single Ed Noted Improved Positive Predicive Value for Severe sepsis/septic shock identification Without affection sensitivity (11). Conclusion In summary, the centiles of RR and RR derived from more than 1 million children seen in the ed of hospitals in most adults were often different from the centiles that are currently derived in children Come in the ED and the vital thresholds of seals based on consensus. We believe that our data provides a reliable representation of HR and RR distributions in stressed children seen in the ED that do not require hospitalization. These data could be used to create algorithms within EHR to develop pragmatic risk scores that increase sensitivity and specificity and reduce characteristic alarm fatigue of thresholds of dichotic vital signs. We also believe that these parameters can help establish better alarm nimp PALS. As hard, the data can better inform the creation of specific disease tools of diseases. Data and material availability The data sets used and analyzed during the present study are available by the corresponding author, but the restrictions apply to the availability of these data since they were obtained through a written agreement with Cerner Corporation and by Therefore they are not available pãºblico. The data may be available by the author under reasonable requests and with permission from Cerner Corporation. Declaration of the technique since we analyzed unidentified closing data, this is not investigation of human subjects. Author contributions RS, SG, and Az each made substantial contributions to the conception and from the study. The RS performed the analysis and derived the centile curves and the z-scores. RS and AZ jointly drafted and the three authors critically revised the manuscript for important intellectual content.
